

# Few-Electron Bubbles in Superfluid Helium Gas

## Why in News

Recently, Scientists at the **Indian Institute of Science (IISc)**, Bangalore for the first time discovered **two species of Few-Electron Bubbles (FEBs) in Superfluid Helium Gas.**

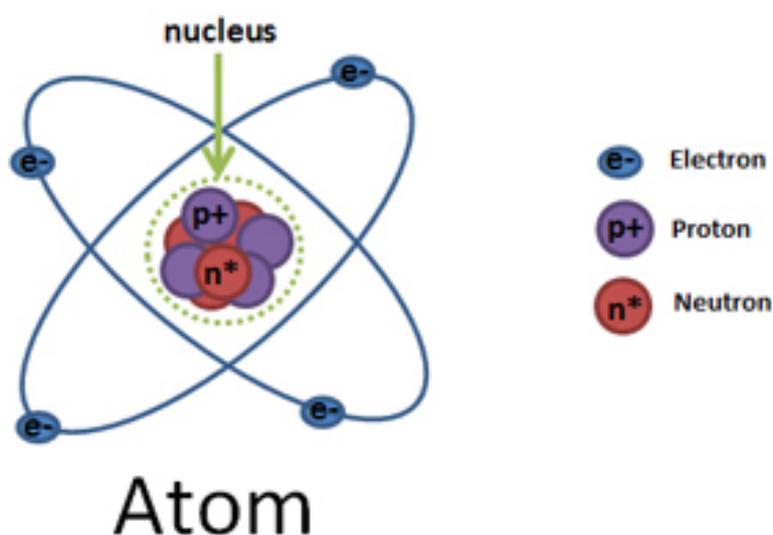

## Helium

- It is a chemical element with the **symbol He and atomic number 2**. The British chemist **Sir William Ramsay** discovered the **existence of helium on Earth in 1895**.
- It is a **colourless, odourless, tasteless, non-toxic, inert, monatomic gas**, the first in the noble gas group in the periodic table.
- Its **boiling point is the lowest among all the elements**.

## Electrons

- **Matter is made up of atoms**, which are the basic units of chemical elements such as hydrogen, helium or oxygen.
- Atoms are **made up of three particles**: Protons, Neutrons and Electrons.
- Hence, **electrons are the subatomic particles that orbit the nucleus of an atom**. They are generally **negative in charge** and are much **smaller than the nucleus of the atom**.

## Key Points

### ▪ Electron Bubble:

- An electron bubble is the **empty space created around a free electron in a cryogenic gas or liquid**, such as neon or helium. They are typically very small, about **2 nm in diameter** at atmospheric pressure.
- An electron injected into a **superfluid** form of helium creates a **Single Electron Bubble (SEB)** — a cavity that is free of helium atoms and contains only the electron. The shape of the bubble depends on the energy state of the electron.
  - For instance, the bubble is spherical when the electron is in the ground state (i.e. state of lowest energy). There are also **multiple electron bubbles** that contain **thousands of electrons**.
  - **Superfluidity** is the **frictionless flow and other exotic behaviour observed in liquid helium at temperatures near absolute zero** (−273.15 °C), and similar frictionless behaviour of electrons in a superconducting solid. In each case the **unusual behaviour arises from quantum mechanical effects**.

### ▪ Few-Electron Bubbles:

- FEBs, on the other hand, are **nanometre-sized cavities in liquid helium containing just a handful of free electrons**. The number, state, and interactions between free electrons dictate the physical and chemical properties of materials.
  - FEBs form an interesting system that has both **electron-electron interaction and electron-surface interaction**.
  - FEBs were found to be **stable for at least 15 milliseconds** (quantum changes typically happen at much shorter time scales) which would enable researchers to trap and study them.

### ▪ Significance:

#### ◦ Study Properties:

- FEBs can serve as a useful model to study how the energy states of electrons and interactions between them in a material influence its properties.

#### ◦ Decipher Phenomenons:

- There are several phenomena that FEBs can help scientists decipher, such as:
  - Turbulent flows in superfluids and viscous fluids, or the flow of heat in superfluid helium.
  - Just like how **current flows without resistance in superconducting materials** at very low temperatures, **superfluid helium also conducts heat efficiently at very low temperatures**.
