

Trigonopterus Corona

Why in News

Recently, scientists have discovered a **new species of beetle named Trigonopterus corona on the Indonesian island of Sulawesi.**

- It is not the only insect species to be named after the pandemic. In April 2021, a **new species of caddisfly** (a moth-like insect) was collected near a stream in Kosovo, and named ***Potamophylax coronavirus***.

Key Points

- It has been named on pandemic which reflects the large impact of the [Covid-19 pandemic](#) on
 - The researcher had been studying this genus (*Trigonopterus*) for the past 15 years and was delayed because Covid-19 pandemic hit.
- *Trigonopterus* is a **hyperdiverse genus of flightless hidden-snout weevils** (*Cryptorhynchinae*) ranging over the **Indo-Australian-Melanesian archipelago**.
 - Weevils are often called **flour bugs** because that is where they are frequently found, they are a type of **beetle with an elongated snout**.
- The genus *Trigonopterus* originated in Northern Australia and rapidly diversified in New Guinea before colonizing Sulawesi and dispersing further west to Sundaland (a bio-geographical area of south-eastern Asia).

Island of sulawesi

this project.

- It is **one of the four Greater Sunda Islands of Indonesia**. It is a curiously shaped island with four distinct peninsulas that form **three major gulfs, Tomini (the largest) on the northeast, Tolo on the east, and Bone on the south.**
 - The island group features the islands of Java, Sumatra, Borneo, and Sulawesi.
- The island is highly mountainous, with some active volcanoes, but there are large plains on the southern peninsula and in the south-central part of the island on which **rice is grown.**
- The **highest peak is Mount Rantekombola, or Mario**, at 11,335 feet.
