

## **Increased Emissions of N20**

## Why in News

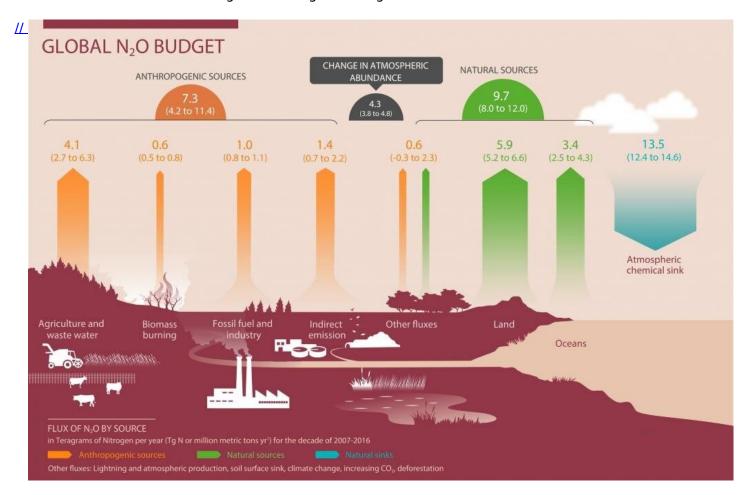

According to a recent research paper, human emissions of <u>nitrous oxide</u> ( $N_2O$ ) have increased by 30% between 1980 and 2016.

 The research was conducted through an international collaboration between the International Nitrogen Initiative (INI) and the Global Carbon Project of <u>Future Earth</u>, a partner of the World Climate Research Programme.

## **Key Points**

- Nitrous Oxide (N<sub>2</sub>O):
  - It is a greenhouse gas (GHG) 300 times more potent than carbon dioxide (CO<sub>2</sub>).
  - It has the **third-highest concentration, after CO<sub>2</sub> and** methane (CH<sub>4</sub>), in Earth's atmosphere among GHGs responsible for global warming.
  - N<sub>2</sub>O is also the **only remaining threat to the <u>ozone</u>** (O<sub>3</sub>) **layer,** for it accumulates in the atmosphere over a long period of time, just like CO<sub>2</sub>.
  - It can live in the atmosphere for up to 125 years.
  - Its global concentration levels have increased from **270 parts per billion** (ppb) in 1750 to **331 ppb in 2018**, a jump of 20%.
    - The growth has been the quickest in the past five decades because of human emissions.
- Research and the Study:
  - This is the most comprehensive study of global N<sub>2</sub>O emissions ever published, as it combines both natural and anthropogenic (man-made) sources.
  - The study found that 43% of the total emissions came from human sources and most N<sub>2</sub>O emissions came from emerging countries like India, China and Brazil.
  - Increase in its emissions means that the climatic burden on the atmosphere is
    increasing from non-carbon sources as well, while the major focus of global climate
    change negotiations is currently centred on carbon, its emissions and mitigation.
  - It also highlighted the dichotomy of the <u>climate crisis</u> and global <u>food security</u>.
    - A major proportion of the N<sub>2</sub>O emissions in the last four decades came from the agricultural sector, mainly because of the use of <u>nitrogen-based fertilisers</u>.
    - The growing demand for food and feed for animals will further increase its global emissions, leading to a direct conflict between the way countries are feeding people and stabilising the climate.
- Suggestions:
  - There are well-established practices and technologies like crop and manure management, the <u>use of bio-fertilisers</u>, to mitigate N<sub>2</sub>O emissions which need to be utilised to their full extent.
  - Revised industrial and agricultural policies at the global level will reduce such

- emissions considerably.
- Reducing GHGs emissions will also have the co-benefits of reduced air and water pollution.
- There is a need to bring the non-carbon sources under the major global climate change negotiations.
- It is possible to slow down N<sub>2</sub>O emissions if countries implement the <u>United Nations</u>
   Global Campaign on Sustainable Nitrogen Management, 2019 held in Colombo, Sri Lanka.
  - The focus of the event was to finalise the **Colombo Declaration**, a follow **up on the** <u>UNEA 4 Resolution on Sustainable Nitrogen Management</u> which aims to further the dialogue on Nitrogen management.
