

Monkeypox

Why in News

Recently, the US started surveillance on people travelling from Nigeria, who may have had contact with the individuals infected with Monkeypox.

Key Points

About:

- It is a viral <u>zoonotic disease</u> (transmission from animals to humans) and is identified as a pox-like disease among monkeys hence it is named Monkeypox. It is endemic to Nigeria.
- It is caused by monkeypox virus, a member of the Orthopoxvirus genus in the family Poxviridae.
- The natural host of the virus remains undefined. But the disease has been reported in many animals.
 - Animals known to be sources of Monkeypox virus include monkeys and apes, a
 variety of rodents (including rats, mice, squirrels and prairie dogs) and rabbits.

Outbreaks:

- It was first reported in 1958, in monkeys in the **Democratic Republic of Congo (DRC)** and in humans in 1970, also in the DRC.
- In 2017, Nigeria experienced the largest documented outbreak, 40 years after the last confirmed case.
- Subsequently, the disease has been reported in many West and Central African countries.

Symptoms:

- Infected people break out in a rash that looks a lot like chicken pox. But the fever, malaise, and headache from Monkeypox are usually more severe than in chicken pox infection.
- In the early stage of the disease, Monkeypox can be distinguished from smallpox because the lymph gland gets enlarged.

Transmission:

- Primary infection is through direct contact with the blood, bodily fluids, or cutaneous or mucosal lesions of an infected animal. Eating inadequately cooked meat of infected animals is also a risk factor.
- Human-to-human transmission can result from close contact with infected respiratory tract secretions, skin lesions of an infected person or objects recently contaminated by patient fluids or lesion materials.
- Transmission can also **occur by inoculation or via the placenta** (congenital monkeypox).

Vulnerability:

- It spreads rapidly and can cause one out of ten deaths if infected.
- Treatment and Vaccine:
 - There is no specific treatment or vaccine available for Monkeypox infection. In the past, the anti-smallpox vaccine was shown to be 85% effective in preventing Monkeypox.
 - But the world was declared free of smallpox in 1980 so the vaccine isn't widely available anymore.
 - Currently, there is no global system in place to manage the spread of Monkeypox, with each country struggling to contain any outbreak whenever it occurs.

Way Forward

- Improved surveillance and response, raise awareness of the disease and avoid contact with wild animals, especially monkeys.
- Any animals that might have come into contact with an infected animal should be quarantined, handled with standard precautions and observed for monkeypox symptoms for 30 days.
- It is important to refocus attention on other diseases. There is a drop in the number of reported cases of endemic diseases as people are not seeking care in health facilities, owing to Covid-19.
