

Mutated Novel Coronavirus

Why in News

A mutated variant of the novel Coronavirus has been associated with recent infections in England.

The virus has undergone several mutations since it first infected humans.

Key Points

- The New Mutant Coronavirus:
 - The mutant virus has been identified as N501Y and is likely to be a mutation in the spike protein.
 - It is the coronavirus spike protein that binds to a human protein to initiate the process of infection.
 - Changes here could possibly affect how the virus behaves in terms of its ability to infect, or cause severe disease, or escape the immune response made by vaccines.
 - There has been a single nucleotide change in one portion of the spike protein, so there would be **no bearing on the disease biology or even diagnostics.**
- Effect on Infection and Vaccination:
 - Several coronavirus vaccines are designed to create antibodies targeting the spike protein.
 - The vaccines **target multiple regions on the spike**, while a mutation refers to a change in a single point. If there is **one mutation**, it does not mean vaccines would not work.
 - All SARS-CoV-2 strains are genetically similar to one another, and scientists do not
 expect these mutations to have a significant impact on their ability to cause more
 severe disease than what has been observed so far.
 - Many mutations mean nothing at all, or at least are more successful for reasons not known.
 - For instance a different strain may be more transmissible, but cause less disease.
 - Researchers need to monitor the mutations as there is no evidence that the new strain
 in the UK is more transmissible or more severe/resistant to treatment or
 vaccination.
- Mutant Variant in India: Researchers have not seen this variant in India.
- Earlier Mutation:
 - D614G Mutation: This particular mutation aided the virus in attaching more efficiently with the ACE2 receptor in the human host, thereby making it more successful in entering a human body than its predecessors.
 - **D614G** showed increased infectivity but it also displayed greater ability at attaching itself to the cell walls inside an individual's nose and throat, increasing the viral load.

Mutation

- A mutation means a change in the genetic sequence of the virus.
- In the case of SARS-CoV-2, which is an <u>Ribonucleic acid (RNA)</u> virus, a mutation means a change in the sequence in which its molecules are arranged.
 - **SARS-CoV-2** is the virus that causes **Covid-19**.
 - RNA is an important biological macromolecule that is present in all biological cells.
 - Principally **involved in the synthesis of proteins, carrying the messenger instructions from** <u>Deoxyribonucleic Acid (DNA)</u>, which itself contains the genetic instructions required for the development and maintenance of life.

he Vision

- DNA is an organic chemical that contains genetic information and instructions for protein synthesis. It is found in most cells of every organism.
- A mutation in an RNA virus often happens when the virus makes a mistake while it is making copies of itself.
 - Only if the mutation results in a **significant change in the protein structure can the course of a disease be altered.**
