Fabrication of Controlled Nanostructures

Why in News

Recently, the researchers at the **Institute of Nano Science and Technology** (INST) **Mohali** have found a route to fabricate precisely controlled nanostructures of desired geometry and location on 2D materials, through a rapid one-step low power laser writing process.

 INST, Mohali is an autonomous institute under the Department of Science and Technology (DST).

Key Points

- INST developed a hybrid Surface-Enhanced Raman Spectroscopy (SERS) platform of Molybdenum disulfide (MoS2, an inorganic compound) nanostructure decorated with gold NanoParticles (AuNPs).
 - SERS is a commonly used sensing technique in which inelastic light scattering by molecules is greatly enhanced when the molecules are adsorbed onto corrugated metal surfaces such as silver or gold nanoparticles (NPs).
 - It enhances the Raman scattering light from molecules, thus leading to effective analysis of the molecules.
- Direct laser writing (3D printing for microscopic world) was used to engineer the artificial edges on the surface of MoS₂ which created localized hotspots with precision and control.
 - A focused laser beam of meagre power of a conventional Raman spectrometer was used which enables the superior deposition of AuNPs along the artificial edges.
 Nanostructuring was done on the 2D MoS₂ sheet.
- The hybrid SERS platform offers controlled formation of localized hotspots for ultrasensitive and reproducible detection of analytes (substances whose chemical constituents are being identified and measured).
- Significance:
 - This research will open a new avenue for the development of commercialized SERS substrates (a silicon wafer coated with a metal like gold or silver) with a localized detection capability of analytes.
 - SERS detection has been emerging as a powerful **tool for the detection of a** variety of analytes due to its very high sensitivity and fingerprinting recognition capabilities.
 - This will also shed new light in the SERS sensing of biological and chemical molecules.
 - The technology can be used in combination with an antibody for the spectroscopic detection of various **biomarkers** (an objective measure that captures what is happening in a cell or an organism at a given moment).

Raman Effect

• It is a phenomenon in **spectroscopy** discovered by the eminent **physicist Sir Chandrasekhara**

Venkata Raman on 28th February 1928.

- In his honour, 28th February is celebrated as **National Science Day** in India.
- In 1930, he got a <u>Nobel Prize</u> for this remarkable discovery and this was the first Nobel Prize for India in the field of Science.
- Raman effect is the inelastic scattering of a photon by molecules which are excited to higher vibrational or rotational energy levels. It is also called Raman scattering.
 - In simpler words, it is a change in the wavelength of light that occurs when a light beam is deflected by molecules.
 - When a beam of light traverses a dust-free, transparent sample of a chemical compound, a small fraction of the light emerges in directions other than that of the incident (incoming) beam.

The Vision

- Most of this scattered light is of unchanged wavelength. A small part, however, has wavelengths different from that of the incident light and its presence is a result of the Raman Effect.
- The Raman effect forms the basis for Raman spectroscopy which is used by chemists and physicists to gain information about materials.
 - **Spectroscopy** is the study of the interaction between matter and electromagnetic radiation.
