Influenza and Bacterial Infection

Why in News

Recently, researches at **Sweden's Karolinska Institute** have come out with findings on **superinfections** and have also highlighted that **influenza makes people more susceptible to bacterial infections.**

Key Points

- Superinfections: These are infection occurring after or on top of an earlier infection, especially following treatment with broad-spectrum antibiotics. It is an overgrowth of an opportunistic pathogen from the bacterial or yeast imbalance of systemic antibiotics.
 - For example, influenza is caused by a virus, but the most common cause of death in influenza patients is secondary <u>pneumonia</u>, which is caused by bacteria.
 - However, the **reason** behind influenza infections leading to an increased risk of bacterial pneumonia is **not known**.
- Case study of Spanish Flu:
 - It was an influenza pandemic that swept across the world in the year 1918-1920.
 - It disproportionately hit young healthy adults and important reason for this was superinfections caused by bacteria, in particular pneumococci.
 - **Pneumococcal infections** are the most common cause of community acquired **pneumonia** and a leading global cause of death.
 - A prior influenza virus infection is often followed by a pneumococcal infection.
- Findings of the Research:
 - When an individual is **infected by influenza** different **nutrients and antioxidants**, **such as vitamin C**, leak from the blood.
 - The absence of nutrients and antioxidants creates a favourable environment for bacteria in the lungs.
 - The bacteria **adapt to the inflammatory environment** by **increasing** the production of an enzyme called **High temperature requirement A** (HtrA).
 - The presence of HtrA weakens the immune system and promotes bacterial growth in the influenza-infected airways.
 - The ability of pneumococcus to grow seems to depend on the nutrient-rich environment with its higher levels of antioxidants that occurs during a viral infection, as well as on the bacteria's ability to adapt to the environment and protect itself from being eradicated by the immune system.
- Significance:
 - The results could be **used to find new therapies for double infections between the influenza virus and pneumococcal bacteria.**
 - A possible strategy can therefore be **use of protease inhibitors to prevent pneumococcal growth** in the lungs.

- The information can contribute to the research on Covid-19.
 - However, it is still not known if **Covid-19 patients are also sensitive to such secondary bacterial infections.**

Influenza

- It is a viral infection that attacks the respiratory system i.e. nose, throat and lungs and is commonly called the flu.
- **Symptoms:** Fever, chills, muscle aches, cough, congestion, runny nose, headaches and fatigue.
- Common Treatment:
 - Flu is primarily treated with **rest and fluid intake** to allow the body to fight the infection on its own.
 - Paracetamol may help cure the symptoms but Non Steroidal Anti-inflammatory Drugs (NSAIDs) should be avoided. An annual vaccine can help prevent the flu and limit its complications.
- Young children, older adults, pregnant women and people with chronic disease or weak immune systems are at high risk.

Pneumonia

- It is an infection that inflames the air sacs in one or both lungs. The air sacs may fill with fluid or pus.
- Cause: Variety of organisms, including bacteria, viruses and fungi.
- Symptoms: Cough with phlegm or pus, fever, chills and difficulty breathing.
- Treatment: Antibiotics can treat many forms of pneumonia. Some forms of pneumonia can be prevented by vaccines.
- The infection can be life-threatening to anyone, but particularly to infants, children and people over 65.
