

# **Delhi Sero-Survey**

## Why in News

Recently, the **National Centre for Disease Control (NCDC)** conducted a **sero-surveillance study** for **Covid-19** in **New Delhi.** 

 NCDC is under administrative control of the Directorate General of Health Services in the Union Ministry of Health and Family Welfare.

# **Key Points**

- Sero-surveillance:
  - **Detects Specific Antibodies:** It seeks to assess the prevalence of disease in a population by **detecting the presence of specific antibodies** against the virus.
  - Immunity Check: It can also be conducted to check if a person has developed immunity to certain diseases.
  - **Past Infections:** It **indicates past infections** (and which triggered an immune response), and is **not used to detect active infections.**
  - Tested Immunoglobulin G Using ELISA: The Sera (a part of blood) of samples were tested for IgG antibodies and Covid-19 infection using <u>Covid Kavach ELISA kits</u> approved by the Indian Council of Medical Research (ICMR).
    - **IgG** (Immunoglobulin G) is a type of antibody which develops in most Covid-19 patients (infections) at around two weeks after infection and remains in the blood even after recovery.
    - ELISA (Enzyme-Linked Immunosorbent Assay) is a test that detects and measures antibodies in blood
- Coverage of the Latest Study:
  - **Coverage Period**: It was conducted from 27<sup>th</sup> June 10<sup>th</sup> July 2020. It was done when the city was reporting over 3,000 cases a day.
  - Coverage Groups: A total 21,387 samples were randomly collected across the 11 districts of the capital, which were then divided into two groups, of less than 18 years and older.
- Result:
  - 23.48% of the people surveyed had developed IgG antibodies, indicating they had been exposed to the novel coronavirus (SARS-CoV-2) that causes Covid-19, with a large number showing no symptoms (asymptomatic).
- Government's Response:
  - Impact of Proactive Efforts: Only 23.48% were found to be infected in a study carried out in a city with several pockets of dense population, shows that the proactive efforts by the government to prevent the spread of Covid-19, including prompt lockdown, effective containment and surveillance measures, contact tracing and tracking, as well as citizens' compliance had yielded benefits.

- **Challenges:** The remaining proportion of the population (about 77%) is still vulnerable to contracting the novel coronavirus infection.
  - Containment measures need to continue with the same rigour.
  - Non-pharmacological interventions such as physical distancing, use of face mask/cover, hand hygiene, cough etiquette and avoidance of crowded places etc. must be followed strictly.
- Concerns:
  - The 23.48% rate of seropositivity cannot be extrapolated over Delhi's entire population.
  - Further, currently there isn't enough scientific data available about the level and duration of immunity that the body will develop after a person tests Covid-positive.
- Sero-surveillance in the Past:
  - ICMR had conducted a pilot sero-survey in April 2020 across 83 districts in 21 states.
  - The initial results, which are being peer-reviewed, suggested that the percentage of the general population that could have been infected was 0.73, with urban areas showing a higher prevalence of about 1.09%.

### Way Forward

- The robust data collected through the study will help in the disease control programme.
- Such scientific studies are extremely important and should be performed from time to time to The Vision understand the lessons from the past.
